Missouri Water Supply Studies

Ву

Jerry Edwards Sherry Chen And Steve McIntosh

FORWARD

The Missouri Department of Natural Resources, Water Resource Center and Missouri's Safe Drinking Water Program has the responsibility of assisting state residences in assuring an adequate and safe water supply. The purpose of the water supply study is to ensure availability of water information for effective decision-making by communities and MoDNR program managers. In addition, this study is expected to be used to determine and allocate existing water supplies. The scope of this study primarily addresses surface water supplies for cities and communities that are expected to experience water shortages during an extended drought. Surface water supplies consist of lakes, rivers and streams and in many cases combinations of both.

PREFACE

This 2005 Water Supply Report is a result of the State's Water Resources Law water planning mandates and done under the direction of the Missouri Drought Assessment Committee. This report and several previous compact disc versions since 2000 have examined communities at risk and their ability to sustain themselves during drought. Many of these water supplies had only months of water supply assured during recent droughts of 1999-2000 and 2002-2004. Most of the communities are located in the northern and western areas of Missouri. These areas are groundwater poor and dependent upon surface water supplies. Four community supplies that draw most of their water supplies from streams in northern and southern Missouri were also examined for firm yield capability. This study is not a complete evaluation of all communities at risk of depletion of water. Updates to this 2005 Water Supply Report are expected and will be produced by compact disc until the next published edition is planned in 2008.

The authors determined that a hard cover edition was needed to better illustrate to a wider audience the critical water quantity needs of many marginal water supplies in the state.

INTRODUCTION

This report was prepared by Missouri Department of Natural Resources to address water supply needs and distribution as a result of extremely dry weather during the drought beginning in 1999 and extending into year 2004. Reservoirs were surveyed by USGS to determine the remaining storage of water for use by cities, communities, and rural water districts. This data is used for drought planning in establishing a network of available water supplies to be used to distribute to needed locations in North and West Central Missouri where water needs are met by surface sources. This report is not meant to be used as a regulatory manual.

Surface water supplies studied and contained in this report are:

Water Supply Systems

- 1. Adrian
- 2. Breckenridge
- 3. Butler
- 4. Brookfield
- 5. Cameron (4 lakes)
- 6. Concordia (E.A. Pape Lake)
- 7. Creighton
- 8. Dearborn
- 9. Drexel
- 10. Garden City (2 lakes)
- 11. Green City
- 12. Hamilton
- 13. Harrison County Rural Water District #1
- 14. Higginsville
- 15. Holden
- 16. James Port
- 17. King City (4 lakes)
- 18. Lamar
- 19. Middle Fork Grand River (Stanberry)
- 20. Milan (3 lakes) (Elmwood, Golf Course and Shatto Lakes)
- 21. Marceline
- 22. Memphis (Lake Show Me and Old City Lake)
- 23. Moberly
- 24. Monroe City RTE "J"
- 25. Ridgeway
- 26. Sedalia (Spring Fork Lake)
- 27. Shelbina
- 28. Unionville (Lake Mahoney and Lake Thunderhead)

Also, this report contains Stream Flow analysis to selected cities obtaining their water supply from rivers and streams. These streams are:

- 1. Black River at Poplar Bluff
- 2. Saline Creek at Perryville
- 3. Shoal Creek at Joplin
- 4. Thompson River at Trenton

In addition, staff gages were installed in five lakes. The gages will aid in making estimates of remaining water supplies and projections during drought periods. These lakes are:

- 1. Butler
- 2. Eagleville, Harrison County Rural Water District #1
- 3. Hamilton
- 4. Marceline
- 5. Monroe City Rte. "J"

Additional lakes planned for study during year 2005 are:

1. Kirksville Forest Lake 2. Kirksville Hazel Creek Lake City Lake #1 3. Bowling Green 4. Bowling Green City Lake #2 City Lake 5. Vandalia

Lakes planned to be surveyed in 2005 and now delayed.

1. Fayette DC Rogers Lake
2. Fayette Old City Lake

ACKNOWLEDGEMENTS

Missouri Drinking Water Program staff members contributed to this project. They provided funding, direction and assistance to the study for communities having or expecting to have water shortage problems. Persons contributing were Jerry Lane, Don Scott, Everett Baker, and Bill Hills.

The United States Geological Survey staff located in Rolla, Missouri made field surveys of lakes.

EXECUTIVE SUMMARY

Missouri Department of Natural Resources Water Resources Program Surface Water Supply Staff has prepared an analysis of 34 communities water systems within Missouri. These include 30 lake systems and four systems using streams as their main water supply source. These systems are mostly in the north and western part of the state. Many of the cities and water supply districts in northern and western Missouri must obtain their supplies from surface water sources in areas where there is either a lack of available wells, poor water quality or both. Two of the southeastern streams studied are the exception. They are Black River at Poplar Bluff and Saline Creek at Perryville.

The objective of this water supply study is to provide technical hydrology and water resource engineering assistance to communities on how to allocate their water supplies during the critical drought of record in order to satisfy their needs during an extended multi-year dry episode. How we manage our water greatly effects the well being and economic stability of the area.

Scenario illustrations are presented for several communities to assist local decision-makers in allocating scarce water supplies. Projecting these scenarios upon current water demands through the most severe drought of record by placing optimum demands upon the reservoirs, streams, and off channel storage facilities in area will assist community leaders in determining if additional water supplies must be found or developed to advert water supply emergencies.

The 1950's drought is the most severe extended drought of record for Missouri. The time period 1951 through 1959, the "drought of record" was used as a base for determining the adequacy of present reservoir water supply capability.

Several of the examined water supply systems are from a collection of surface water sources, which can include several small lakes in series or tandem and often supplemented by in-stream diversion pumps. These analyses were made for some of the most critical supplies. Cities usually use two sources to supply their needs. These sources are lakes and flowing streams. Water stored in lakes comes from rainfall runoff to the lakes. Many of the lakes are too small in size and drainage area to satisfy local needs. As a result, the supply provided by the lakes must be supplemented by other sources. A common practice is to pump from streams into the lakes during high stream flows in an attempt to keep water levels in lakes near full. During droughts one can expect the streams to dry up or stream flow to be so low that pumping cannot be achieved. Basic engineering programs were used to study lake capacities and stream flows.

Staff gages are planned to be or have been installed on five of the lakes. By using these reservoir stage gages and with the analysis of historical droughts, supply projections can be made. We also produced frequency of depletion type charts. These charts can assist engineers to assess water needs and distribution. If an additional step is taken by the local communities to monitor supplies the local operators can project for themselves their remaining storage to empower public works directors on how to allocate existing water supplies.

Because of the gradual increases in demand for water, these charts will also assist in determining the urgency of providing new reservoirs and additional water storage facilities.

Tables one and two show the dependability of water supplies for each system. Not all systems could withstand a drought such as the one in the 1950's with their present demands.

Table 2

^{* 1} year in 50 is the lowest mean monthly flow that is expected to occur one year out of 50 years.

Introduction to Lake Analysis

These analyses were made for the drought of record, which was through the 1950's. At least two conditions are presented in all cases. The first run was made with current demand and the second was to optimize that demand to establish the firm yield. Other runs were made if necessary, such as effects of different schemes of pumping from a creek. If pumping from a stream was incurred, additional runs were made to evaluate effects of pumping.

USDA's Natural Resource Conservation Service reservoir operations computer program "RESOP" was used to make each evaluation. Computations are in one-month increments and represent end of month results. The "RESOP" program uses:

- 1. Lake volume and surface area
- 2. Rainfall
- 3. Runoff
- 4. Lake Evaporation
- 5. Seepage
- 6. Demand or water usage
- 7. Other inflow such as pumping from a stream.

Sources of data used to evaluate remaining storage in each reservoir are:

- Reservoir Storage Reservoirs were surveyed for remaining available storage by the USGS from year 2000 to 2004.
- Time Period The analysis for drought effects was selected to be the 1950's. This was the longest and most severe drought of record.
- Rainfall Rainfall for each water supply lake was the nearest NOAA weather station. If there were missing days in the data, then the next nearest station was used to fill in the gaps.
- Runoff Regional monthly runoff from nearest stream gages were used. If the Runoff did not look to be reasonable, i.e. Runoff greater than rainfall for a certain month, adjustments were made to the runoff by examining each individual rainfall event for that month. To make the runoff determination, five-day rainfall was used to estimate the anticedent moisture. The NRCS cover complex number was used to estimate runoff for each storm. See appendix "A" for an explanation.
- Evaporation The nearest NOAA weather station with pan evaporation data was used. Pan evaporation was then adjusted to lake evaporation.
- Seepage Seepage was estimated based on experience. In north Missouri seepage is very low.
- Demand Demand is the amount of water available for consumptive uses. This value comes from community records.
- Other Other is used to identify other inflow or outflow such as pumping from a stream.

"RESOP" is a DOS program. The users manual and software for the

"RESOP" program are not included in this report but are available on CD upon request.
